

Lecture #25: Transaction Fees

COMS 4995-001:
The Science of Blockchains

URL: <https://timroughgarden.org/s25/>

Tim Roughgarden

Goals for Lecture #25

1. Block size and metering computation.

- transactions fees most naturally priced “per-unit-size”
- in a Turing-complete blockchain, how to measure “transaction complexity”?

2. Transaction fees and first-price auctions.

- FPAs: users submit bids, do price discovery (Bitcoin, Ethereum 2015-21)

3. EIP-1559.

- how Ethereum prices transactions (2021-now)
- moves price discovery largely in-protocol, has deflationary side effects

Block Size

Limited capacity: a blockchain protocol can't process infinite txs/second.

- for a fixed block rate, maximum size of a block is finite

Block Size

Limited capacity: a blockchain protocol can't process infinite txs/second.

- for a fixed block rate, maximum size of a block is finite

Consequence: if demand for tx processing exceeds supply → txs must compete for inclusion. (block proposer will have tough decisions to make)

Block Size

Limited capacity: a blockchain protocol can't process infinite txs/second.

- for a fixed block rate, maximum size of a block is finite

Consequence: if demand for tx processing exceeds supply → txs must compete for inclusion. (block proposer will have tough decisions to make)

Question: what is the “size” of a block?

Block Size

Limited capacity: a blockchain protocol can't process infinite txs/second.

- for a fixed block rate, maximum size of a block is finite

Consequence: if demand for tx processing exceeds supply → txs must compete for inclusion. (block proposer will have tough decisions to make)

Question: what is the “size” of a block?

First thought: size of block = number of txs in it.

Block Size

Limited capacity: a blockchain protocol can't process infinite txs/second.

- for a fixed block rate, maximum size of a block is finite

Consequence: if demand for tx processing exceeds supply → txs must compete for inclusion. (block proposer will have tough decisions to make)

Question: what is the “size” of a block?

First thought: size of block = number of txs in it.

Issue: some txs “more complicated” than others.

Transaction Size

- Idea:** “tx size” \approx amount of resources required to process it.
- size of block then sum of sizes of the txs in it

Transaction Size

Idea: “tx size” \approx amount of resources required to process it.

- size of block then sum of sizes of the txs in it

Challenge: tx consumes multiple types of resources.

- network bandwidth, validator computation, storage

Transaction Size

Idea: “tx size” \approx amount of resources required to process it.

- size of block then sum of sizes of the txs in it

Challenge: tx consumes multiple types of resources.

- network bandwidth, validator computation, storage

Further challenge: resource consumption may depend on specific client implementation and/or validator architecture.

Transaction Size

Idea: “tx size” \approx amount of resources required to process it.

Challenges: tx consumes multiple types of resources; resource consumption may depend on implementation/architecture.

Bitcoin (pre-Segwit): tx size := description length (in bytes).

- typical tx size 250 bytes
- maximum block size = 1 MB \rightarrow 4000 tx/block (< 7 txs/sec)

Transaction Size

Idea: “tx size” \approx amount of resources required to process it.

Challenges: tx consumes multiple types of resources; resource consumption may depend on implementation/architecture.

Bitcoin (pre-SegWit): tx size := description length (in bytes).

Bitcoin (post-SegWit): redefined “size” of a transaction to:

$.25 * (\# \text{ of bytes used for witness data}) + (\# \text{ of additional bytes used})$

– ➔ maximum block size now effectively 4MB (if entirely witness data)

0000000000000000000017296d2ac7ffde35a988c17c6d8728a3ed0036853d796

Block was mined on 2025-04-07 07:01:06 GMT -4. It has 1 confirmation on the Bitcoin blockchain. There are 2800 transactions in block 891332.

Metering Computation in Ethereum

Metering Computation in Ethereum

Note: in a Turing-complete VM, even a “small” tx could run forever.

Metering Computation in Ethereum

Note: in a Turing-complete VM, even a “small” tx could run forever.

Solution: force user to prepay for computation, tx aborts and is rolled back if budget is exhausted. (important: txs are atomic)

Example: USDC Transfer

Metering Computation in Ethereum

Note: in a Turing-complete VM, even a “small” tx could run forever.

Solution: force user to prepay for computation, tx aborts and is rolled back if budget is exhausted. (important: txs are atomic)

Metering Computation in Ethereum

Note: in a Turing-complete VM, even a “small” tx could run forever.

Solution: force user to prepay for computation, tx aborts and is rolled back if budget is exhausted. (important: txs are atomic)

- associate an amount of “gas” with each EVM opcode
 - EVM opcodes = instruction set for VM code in Ethereum’s VM
 - add two numbers = 3 units of gas; evaluate SHA-256 = 30 units

Metering Computation in Ethereum

Note: in a Turing-complete VM, even a “small” tx could run forever.

Solution: force user to prepay for computation, tx aborts and is rolled back if budget is exhausted. (important: txs are atomic)

- associate an amount of “gas” with each EVM opcode
 - EVM opcodes = instruction set for VM code in Ethereum’s VM
 - add two numbers = 3 units of gas; evaluate SHA-256 = 30 units
- user prepays for gas

Metering Computation in Ethereum

Note: in a Turing-complete VM, even a “small” tx could run forever.

Solution: force user to prepay for computation, tx aborts and is rolled back if budget is exhausted. (important: txs are atomic)

- associate an amount of “gas” with each EVM opcode
 - EVM opcodes = instruction set for VM code in Ethereum’s VM
 - add two numbers = 3 units of gas; evaluate SHA-256 = 30 units
- user prepays for gas
- run out of gas mid-execution → tx aborted and rolled back

Metering Computation in Ethereum

Note: in a Turing-complete VM, even a “small” tx could run forever.

Solution: force user to prepay for computation, tx aborts and is rolled back if budget is exhausted. (important: txs are atomic)

- associate an amount of “gas” with each EVM opcode
- user prepays for gas (recall “gas limit” and “gas price” fields)
- run out of gas mid-execution → tx aborted and rolled back

Current block size: target = 18 million gas/block, max = 36 million.

- typically a couple hundred txs/block (≈ 15 txs/sec)

Transaction Fees

- **transaction fee** = price paid (per unit “size”) for tx execution
 - generally priced (under the hood) in blockchain protocol’s native currency
 - potential source of validator rewards (in addition to block/staking rewards)

Transaction Fees

- **transaction fee** = price paid (per unit “size”) for tx execution
 - generally priced (under the hood) in blockchain protocol’s native currency
 - potential source of validator rewards (in addition to block/staking rewards)
- **regime #1**: abundant blockspace (supply > demand)
 - nominal tx fee generally sufficient (still want to deter spam)

Transaction Fees

- **transaction fee** = price paid (per unit “size”) for tx execution
 - generally priced (under the hood) in blockchain protocol’s native currency
 - potential source of validator rewards (in addition to block/staking rewards)
- **regime #1**: abundant blockspace (supply > demand)
 - nominal tx fee generally sufficient (still want to deter spam)
- **regime #2**: scarce blockspace (demand > supply)
 - have to choose, would like to include the “most valuable” txs

Transaction Fees

- **transaction fee** = price paid (per unit “size”) for tx execution
 - generally priced (under the hood) in blockchain protocol’s native currency
 - potential source of validator rewards (in addition to block/staking rewards)
- **regime #1**: abundant blockspace (supply > demand)
 - nominal tx fee generally sufficient (still want to deter spam)
- **regime #2**: scarce blockspace (demand > supply)
 - have to choose, would like to include the “most valuable” txs
 - “most valuable” = those willing to pay a suitable price (per unit “size”)
 - if don’t charge fees in-protocol, markets will arise out-of-protocol

Transaction Fees

- **transaction fee** = price paid (per unit “size”) for tx execution
 - generally priced (under the hood) in blockchain protocol’s native currency
 - potential source of validator rewards (in addition to block/staking rewards)
- **regime #1**: abundant blockspace (supply > demand)
 - nominal tx fee generally sufficient (still want to deter spam)
- **regime #2**: scarce blockspace (demand > supply)
 - have to choose, would like to include the “most valuable” txs
 - “most valuable” = those willing to pay a suitable price (per unit “size”)
 - if don’t charge fees in-protocol, markets will arise out-of-protocol
 - price could be set by protocol or by users themselves (or both)

First-Price Auctions (FPAs)

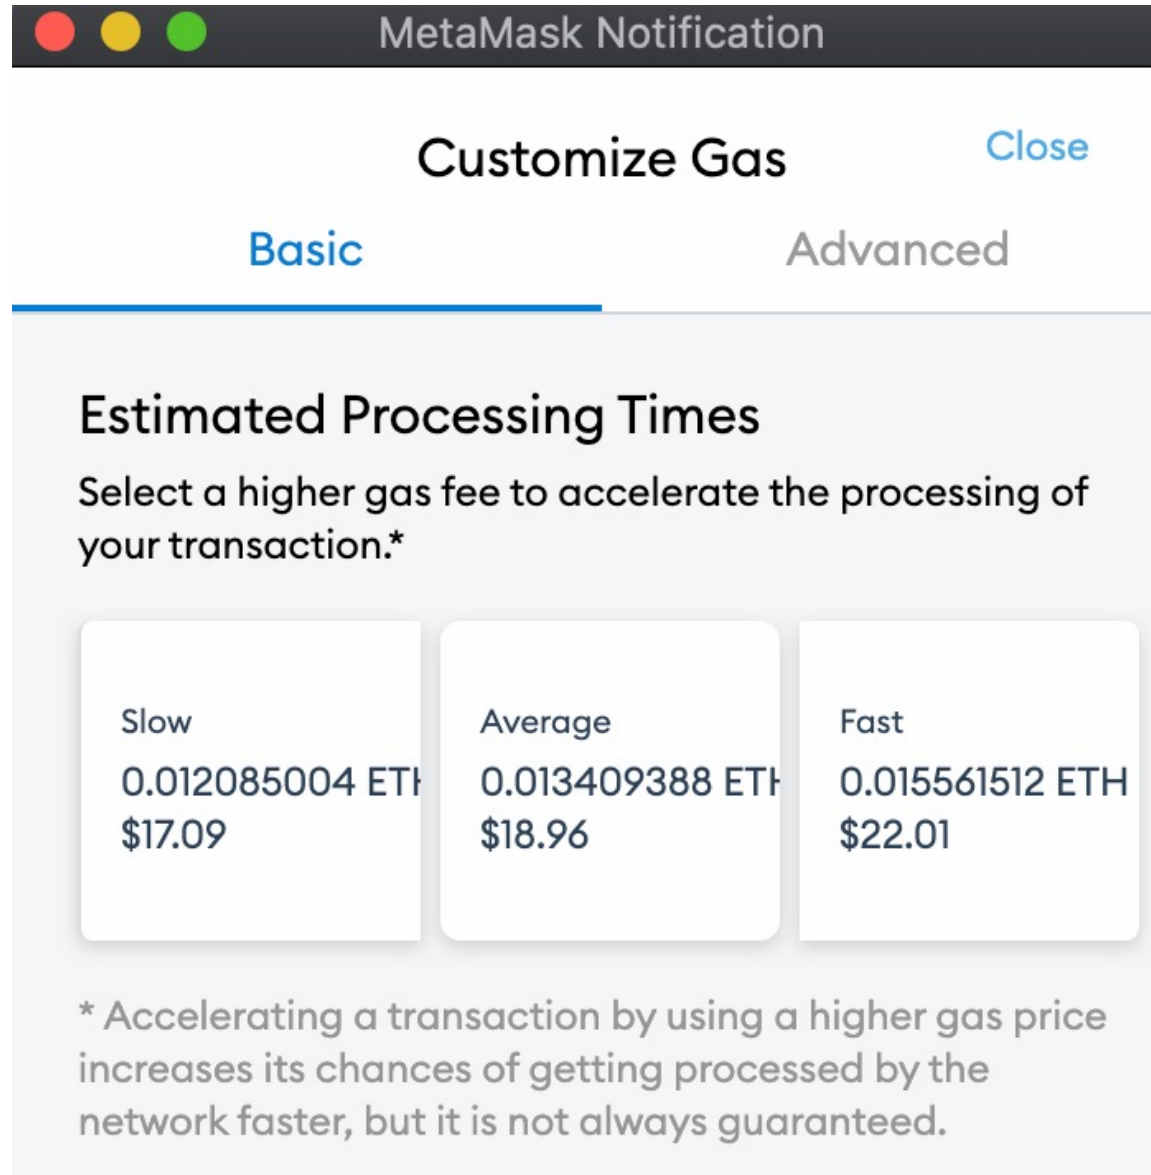

Idea: let “market do the work,” users/wallets to the price discovery.

First-Price Auctions (FPAs)

Idea: let “market do the work,” users/wallets to the price discovery.

First-price auction:

- each submitted tx includes a bid (per-unit “size”)
 - e.g., suggested by user’s wallet based on recently produced blocks

First-Price Auctions (FPAs)

Idea: let “market do the work,” users/wallets to the price discovery.

First-price auction:

- each submitted tx includes a bid (per-unit “size”)
 - e.g., suggested by user’s wallet based on recently produced blocks
- on inclusion in a block, bid transferred to producer of that block
 - e.g., the leader of the current view
 - expect block producer to pack its block with the highest-bidding txs

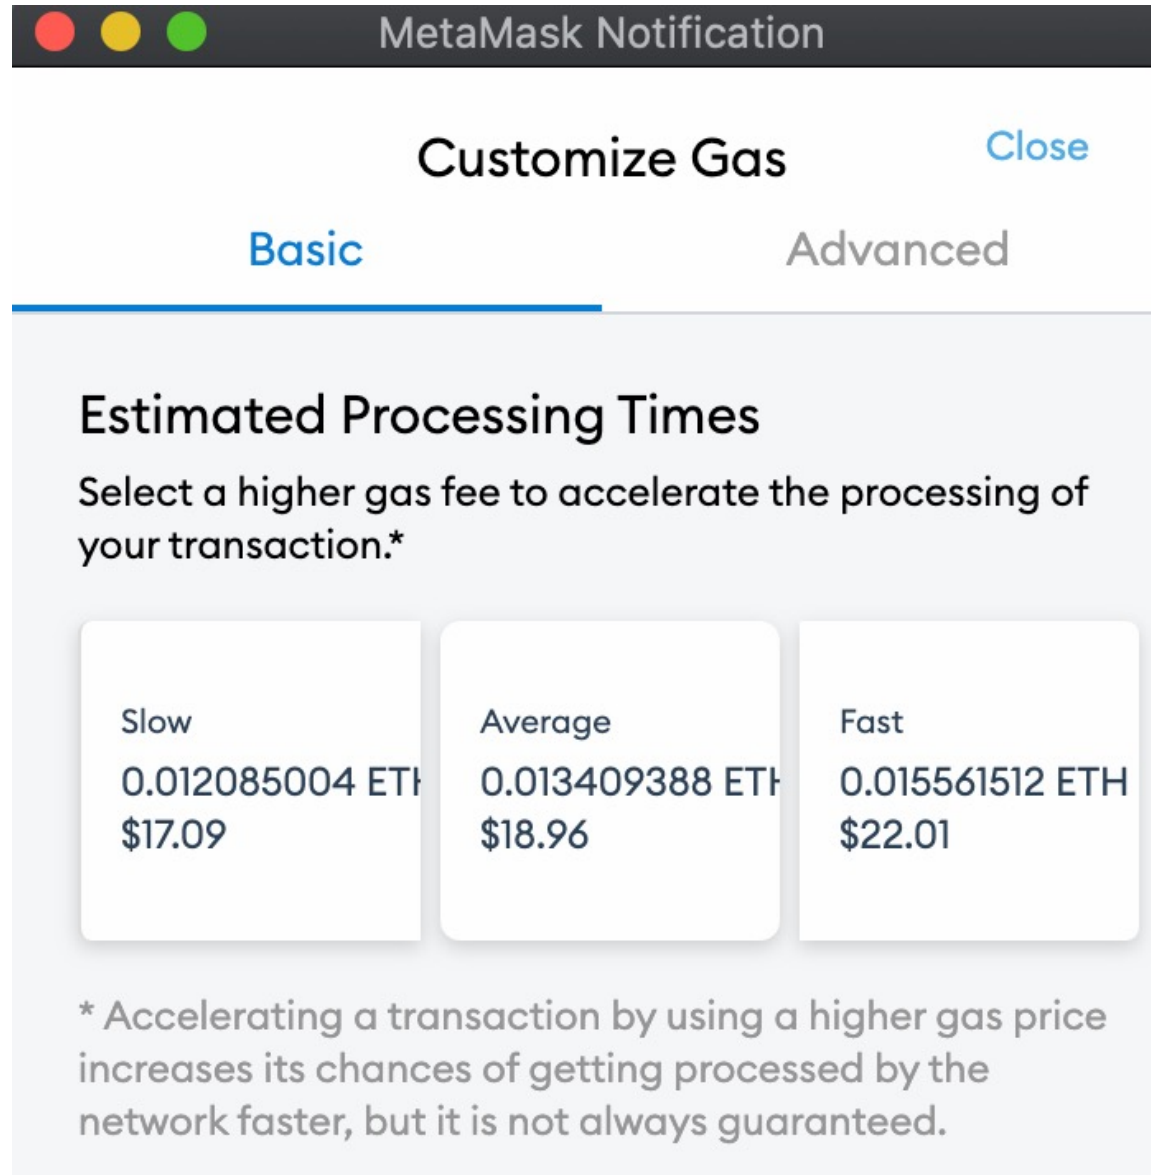

First-Price Auctions (FPAs)

Idea: let “market do the work,” users/wallets to the price discovery.

First-price auction:

- each submitted tx includes a bid (per-unit “size”)
 - e.g., suggested by user’s wallet based on recently produced blocks
- on inclusion in a block, bid transferred to producer of that block
 - e.g., the leader of the current view
 - expect block producer to pack its block with the highest-bidding txs

Issue with FPAs: tricky to figure out the best bid.

First-Price Auctions (FPAs)

Idea: let “market do the work,” users/wallets to the price discovery.

First-price auction:

- each submitted tx includes a bid (per-unit “size”)
- on inclusion in a block, bid transferred to producer of that block

Issue with FPAs: tricky to figure out the best bid.

- bid too high → pay more than you needed to (in hindsight)

First-Price Auctions (FPAs)

Idea: let “market do the work,” users/wallets to the price discovery.

First-price auction:

- each submitted tx includes a bid (per-unit “size”)
- on inclusion in a block, bid transferred to producer of that block

Issue with FPAs: tricky to figure out the best bid.

- bid too high → pay more than you needed to (in hindsight)
- bid too low → excluded (even though you would have been willing to pay enough for inclusion)

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)
- moves price discovery largely in-protocol (cf., FPs)

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)
- moves price discovery largely in-protocol (cf., FPAs)

Note: can't give base fee revenues to the block producer.

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)
- moves price discovery largely in-protocol (cf., FPAs)

Note: can't give base fee revenues to the block producer.

- **reason:** collusion between users and block producer

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)
- moves price discovery largely in-protocol (cf., FPAs)

Note: can't give base fee revenues to the block producer.

- **reason:** collusion between users and block producer
 - either through off-chain agreement or facilitated via smart contracts
 - users bid r on-chain (for eligibility), submit off-chain bids to block producer
 - block producer includes highest-bidding txs, refunds (r -bid) off-chain
 - evades the base fee r , equivalent to an FPA!

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)
- moves price discovery largely in-protocol (cf., FPAs)

Note: can't give base fee revenues to the block producer.

- **reason:** collusion between users and block producer

Solution: burn the base fee revenue! (i.e., remove coins from circulation)

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)
- moves price discovery largely in-protocol (cf., FPAs)

Note: can't give base fee revenues to the block producer.

- **reason:** collusion between users and block producer

Solution: burn the base fee revenue! (i.e., remove coins from circulation)

- **side effect:** offsets staking rewards, decreases inflation rate

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)
- moves price discovery largely in-protocol (cf., FPAs)

Note: can't give base fee revenues to the block producer.

- **reason:** collusion between users and block producer

Solution: burn the base fee revenue! (i.e., remove coins from circulation)

- **side effect:** offsets staking rewards, decreases inflation rate
- any excess ($\text{bid} - r$) transferred to block producer

Example: USDC Transfer

[illegible]

user/wallet specifies “tip/priority fee” and “fee cap”

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)

Note: can't give base fee revenues to the block producer.

- **reason:** collusion between users and block producer

Solution: burn the base fee revenue! (i.e., remove coins from circulation)

- **side effect:** offsets staking rewards, decreases inflation rate
- any excess $(\text{bid} - r)$ transferred to block producer (BP)

EIP-1559

Key idea #1: each block has a “base fee” $r > 0$.

- minimum bid eligible for inclusion (OK to bid higher than r)

Note: can't give base fee revenues to the block producer.

- **reason:** collusion between users and block producer

Solution: burn the base fee revenue! (i.e., remove coins from circulation)

- **side effect:** offsets staking rewards, decreases inflation rate
- any excess ($\text{bid} - r$) transferred to block producer (BP)

Guarantee: user-BP collusion no longer an issue (“OCA-proof”).

Setting the Base Fee

Question: how to set r ?

Setting the Base Fee

Question: how to set r ?

Ideal base fee: r = “market-clearing price.”

Setting the Base Fee

Question: how to set r ?

Ideal base fee: r = “market-clearing price.”

- total size of txs willing to pay r (per-unit-size) exactly fills up block
 - 100% utilization, and used exactly by the most valuable txs

Setting the Base Fee

Question: how to set r ?

Ideal base fee: r = “market-clearing price.”

- total size of txs willing to pay r (per-unit-size) exactly fills up block
 - 100% utilization, and used exactly by the most valuable txs

Issue: as demand varies over time, so does market-clearing price.

Setting the Base Fee

Question: how to set r ?

Ideal base fee: r = “market-clearing price.”

- total size of txs willing to pay r (per-unit-size) exactly fills up block
 - 100% utilization, and used exactly by the most valuable txs

Issue: as demand varies over time, so does market-clearing price.

Solution: compute base fee via local search.

Setting the Base Fee

Question: how to set r ?

Ideal base fee: r = “market-clearing price.”

- total size of txs willing to pay r (per-unit-size) exactly fills up block
 - 100% utilization, and used exactly by the most valuable txs

Issue: as demand varies over time, so does market-clearing price.

Solution: compute base fee via local search.

- total size of eligible txs $>$ block size \rightarrow increase r
- total size of eligible txs $<$ block size \rightarrow decrease r

Variable-Size Blocks

Idea: compute base fee via local search.

- increase/decrease r if size of eligible txs more than/less than block size

Variable-Size Blocks

Idea: compute base fee via local search.

- increase/decrease r if size of eligible txs more than/less than block size

Issue: excluded txs not recorded on-chain.

- can't differentiate r = market-clearing price vs. r = way too low

Variable-Size Blocks

Idea: compute base fee via local search.

- increase/decrease r if size of eligible txs more than/less than block size
- **issue:** can't differentiate r = market-clearing price vs. r = way too low

Key idea #2: allow variable-size blocks.

Variable-Size Blocks

Idea: compute base fee via local search.

- increase/decrease r if size of eligible txs more than/less than block size
- **issue:** can't differentiate r = market-clearing price vs. r = way too low

Key idea #2: allow variable-size blocks.

- set target block size = C (e.g., 18 million gas)

Variable-Size Blocks

Idea: compute base fee via local search.

- increase/decrease r if size of eligible txs more than/less than block size
- **issue:** can't differentiate r = market-clearing price vs. r = way too low

Key idea #2: allow variable-size blocks.

- set target block size = C (e.g., 18 million gas)
- allow blocks of size up to $2C$ (36 million gas)

Variable-Size Blocks

Idea: compute base fee via local search.

- increase/decrease r if size of eligible txs more than/less than block size
- **issue:** can't differentiate r = market-clearing price vs. r = way too low

Key idea #2: allow variable-size blocks.

- set target block size = C (e.g., 18 million gas)
- allow blocks of size up to $2C$ (36 million gas)
- whenever a block has size $< C \rightarrow$ decrease r for next block
- whenever a block has size $> C \rightarrow$ increase r for next block

| Block | Slot | Age | Txn | Fee Recipient | Gas Used | Gas Limit | Base Fee | Reward | Burnt Fees (ETH) |
|----------|--|-------------|-----|--|---------------------|------------|------------|-------------|-------------------|

Variable-Size Blocks

Idea: compute base fee via local search.

- increase/decrease r if size of eligible txs more than/less than block size
- **issue:** can't differentiate r = market-clearing price vs. r = way too low

Key idea #2: allow variable-size blocks.

- set target block size = C (e.g., 18 million gas)
- allow blocks of size up to $2C$ (36 million gas)
- whenever a block has size $< C \rightarrow$ decrease r for next block
- whenever a block has size $> C \rightarrow$ increase r for next block
 - in Ethereum, max increase/decrease = 12.5%

Does EIP-1559 Make Bidding Easy?

Recall issue with FPAs: tricky to figure out the best bid.

Does EIP-1559 Make Bidding Easy?

Recall issue with FPAs: tricky to figure out the best bid.

Defn: base fee r is *excessively low* if total size of eligible txs is $> 2C$.

Does EIP-1559 Make Bidding Easy?

Recall issue with FPAs: tricky to figure out the best bid.

Defn: base fee r is *excessively low* if total size of eligible txs is $> 2C$.

Guarantee: if r not excessively low, optimal for users to bid r .

- r acts like a “posted price” for blockspace, a la shopping on Amazon

Does EIP-1559 Make Bidding Easy?

Recall issue with FPAs: tricky to figure out the best bid.

Defn: base fee r is *excessively low* if total size of eligible txs is $> 2C$.

Guarantee: if r not excessively low, optimal for users to bid r .

- r acts like a “posted price” for blockspace, a la shopping on Amazon
- in practice, add nominal “tip” to strictly incentivize tx inclusion

Does EIP-1559 Make Bidding Easy?

Recall issue with FPAs: tricky to figure out the best bid.

Defn: base fee r is *excessively low* if total size of eligible txs is $> 2C$.

Guarantee: if r not excessively low, optimal for users to bid r .

- r acts like a “posted price” for blockspace, a la shopping on Amazon
- in practice, add nominal “tip” to strictly incentivize tx inclusion
- **otherwise:** EIP-1559 effectively reverts to an FPA
 - if need to compete with other eligible txs for inclusion, will bid above r

Does EIP-1559 Make Bidding Easy?

Recall issue with FPAs: tricky to figure out the best bid.

Defn: base fee r is *excessively low* if total size of eligible txs is $> 2C$.

Guarantee: if r not excessively low, optimal for users to bid r .

- r acts like a “posted price” for blockspace, a la shopping on Amazon
- in practice, add nominal “tip” to strictly incentivize tx inclusion
- **otherwise:** EIP-1559 effectively reverts to an FPA
 - if need to compete with other eligible txs for inclusion, will bid above r
 - e.g., if sudden demand spike (NFT drop) + base fee hasn’t caught up yet
